Abstract. We present an automatic approach for instantiating existentially quantified variables in inductive specifications proofs. Our approach uses first-order meta-variables in place of existentially quantified variables and combines logical proof search with rippling techniques. We avoid the non-termination problems which usually occur in the presence of existentially quantified variables. Moreover, we are able to synthesize conditional substitutions for the meta-variables. We illustrate our approach by discussing the specification of the integer square root.

1 Introduction

Constructive type theory [12] offers the unique advantage of total correctness of synthesized programs. In this setting a specification is of the form

$$\forall input.\ \exists output.\ \ spec(input, output)$$

where *input* is a vector of arguments, *output* is a result and *spec* is a proposition describing the required relation between them. A program meeting this specification can be extracted from its proof via the proofs-as-programs principle [3]. This style is widely advocated [13] and supported in a number of implementations such as NuPRL [8]. The application of such systems however is limited by its low degree of automation. In order to overcome this drawback, we suggest incorporating techniques from inductive theorem proving.

The first difficult step within a proof is the choice of the appropriate induction scheme. Different induction schemes result in algorithms which differ in their complexity. In this paper we focus on the second crucial step during the induction step, the instantiation of existentially quantified variables. The witness for an existentially quantified variable corresponds to the recursive calls in the program. Sometimes a case split is necessary before decomposing the existential quantifier. The existentially quantified variables are then instantiated according to the cases.

A standard technique to deal with existentially quantified variables is to use meta-variables in place of the existential witness and allow the application of

Fourth International Conference Artificial Intelligence and Symbolic Computation, Plattsburgh, NY, September 1998. LNAI 1476, pp. 247–258, Springer Verlag, 1998.

logical rules that refine the goal. To complete the proof, a unification procedure provides the instantiation of the meta-variables. In inductive specification proofs, standard unification techniques are not sufficient; we need to rewrite the expression from the induction conclusion towards the application of the corresponding expression in the induction hypothesis. Both expressions have to be equal after some rewriting steps. The crucial question is how can we find a chain of rewriting steps, such that both expressions can be made equal by rewriting in the presence of meta-variables.

In inductive theorem proving, an annotated rewriting technique, called rippling [7, 6], has been used successfully in order to control the rewriting process. However, only little focus has been devoted to the automatic instantiation of existentially quantified variables. In this paper we suggest combining the logic provided by constructive type theory with inductive theorem proving techniques such as rippling, in order to compute valid instantiations for the existentially quantified variables. We use first-order meta-variables during proof search within the sequent calculus. During rippling the meta-variables are treated in the same way as potential "sink variables". We develop a *reverse rippling match* that matches the induction conclusion with the induction hypothesis. If this match is successful, it returns an instantiation for the meta-variables and a rippling sequence, that rewrites the instantiated induction conclusion to the induction hypothesis. With this approach we avoid non-termination problems that usually occur in the presence of existentially quantified variables. Moreover, we check the consistency of the remaining subgoals under the synthesized substitution. During this consistency check, we are able to synthesize constraints that form a case split during the proof. We demonstrate the strength of our approach by discussing the proof of the integer square root specification.

In Section 2, we give a brief introduction to rippling and discuss the rippling approaches for dealing with meta-variables. In Section 3 we describe the general idea of our approach and in 4 we consider the proof of the integer square root. We show step-by-step how we can derive *conditional substitutions* for the existentially quantified variables. In Section 5 we present a more technical description of our method using ML-notation. In Section 6 we describe the formalization in NuPRL. In Section 7 an extension to our technique is presented. We discuss related work concerning program synthesis in Section 8 and finally in Section 9 we outline future work and draw some conclusions.

2 A Brief Introduction to Rippling

Rippling is an annotated rewriting technique that has been successfully applied in inductive theorem proving. Differences between the induction hypothesis (*given*) and the induction conclusion (*goal*) are marked by meta-level annotations, called *wave annotations*. Expressions that appear both in the goal and in the given are called *skeleton*. Expressions that appear in the goal, but not in the given are called *wave-fronts*. The induction (or recursive) variable that is surrounded by a wave-front is called *wave-hole*. *Sinks* are parts of the goal which

correspond to universally quantified variables in the given and are marked by $\lfloor sink \rfloor$. We call the annotated rewrite rules *wave-rules*. To illustrate, consider the following wave-rule which is derived from the recursive definitions of $+$.

$$\boxed{\mathsf{s}(\underline{U})}^{\uparrow} + V \overset{R}{\longmapsto} \boxed{\mathsf{s}(\underline{U + V})}^{\uparrow} \tag{1}$$

In this wave-rule $\mathsf{s}(\dots)$ denotes the wave-front that is marked by a box. The underlined parts $\underline{U}$ resp. $\underline{U + V}$ mark the wave-holes. Intuitively, the position and orientation of the wave-fronts define the direction in which the wave-front has to move within the term tree. An up-arrow $\uparrow$ indicates that the wave-front has to move from a position within the term tree towards the root of the term tree (*rippling-out*). A down-arrow $\downarrow$ moves the wave-front inwards or sideways towards the sink in the term tree, i.e. the sink is filled with the wave-front (*rippling-in*). If rippling succeeds in moving the annotations either to the root of the term tree or to a sink, then rippling terminates successfully and the induction hypothesis matches the induction conclusion. Rippling terminates unsuccessfully if the rewriting process is blocked, i.e. no wave-rule is applicable anymore and the induction hypothesis (given) does not match the induction conclusion (goal).

In Basin & Walsh [2], a calculus for rippling is presented and well-founded measure, called *wave measure* is defined, under which rippling terminates if no meta-variables occur in the goal. The wave measure associates weights to the wave-fronts to measure the width and the size of the wave-front. The *width* of a wavefront is defined by the number of nested function symbols between the root of the wave-front and the wave-hole. The *size* of a wave-front is the number of function symbols and constants in the wave-front. Rewriting is restricted such that each application of a wave-rule is skeleton preserving and measure decreasing according to the defined wave measure.

For instantiating existentially quantified variables via rippling, mainly two approaches have been suggested in the literature. In Bundy *et al.* [6] special existential wave-rules are suggested. Existential wave-rules can be derived from non-existential wave-rules. For example, the existential wave-rule corresponding to wave-rule (1) takes the following form:

$$\exists \boxed{U} : \mathbb{N}.\ \boxed{U} + V \overset{R}{\longmapsto} \exists \boxed{U'} : \mathbb{N}.\ \boxed{s(\underline{U' + V})}^{\uparrow} \tag{2}$$

Unfortunately, the search problem is exacerbated in the presence of existential quantifiers. Another disadvantage of this approach is that the process of existential rippling does not explicitly record the relationship between the non-existential wave-rule (1) and its existential analogue (2), more precisely the relation between U and U'. This does not matter if we are just interested in provability. In program synthesis, however, the identity of the existential witness plays a vital role of defining the program to be synthesized.

Other approaches [1, 10, 16] use meta-annotations; the existentially quantified variable x is replaced by $\boxed{F(\underline{X})}$ where capital letters indicate meta-variables. Middle-out reasoning [9] is used in order to instantiate the function F and its

argument X. This problem requires a computationally expensive higher-order unification. The presence of higher-order variables also leads to non-termination of rippling, as the width and the size of the wave-front cannot be determined.

Our approach overcomes these drawbacks by combining rippling with first–order theorem proving techniques and using an extended matching procedure for finding the witness for the existentially quantified variables.

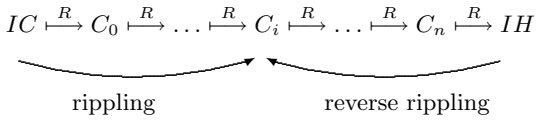
3 Automatic Instantiation of Meta-variables

Our research interest is to automate key steps such as the instantiation of the existentially quantified variable in sequent proofs. By the proofs–as–programs paradigm we are then able to extract a program from the proof of a specification. In Figure 1 an overview of our approach is presented. In order to deal with

1. **Refinement of the step case formula** by applying sequent rules and using meta-variables in place of existential witness
2. **On atomic subgoals**: Matching of the induction hypothesis with induction conclusion is extended by **reverse rippling match** in order to compute valid substitutions for the meta-variables and a rippling sequence
3. **Consistency check**: test, if all subgoals are true under the found substitution

Fig. 1. Automatic instantiation of meta-variables – 3 steps

existentially quantified variables, we suggest first decomposing the existentially quantified formula and use first-order meta-variables in place of the existentially quantified variables. Secondly, an extended matching procedure tries to find a rippling sequence and an instantiation for the meta-variables such that the induction hypothesis term and the corresponding induction conclusion term are equal. Rippling is used to manipulate the atomic subgoals. It rewrites part of the



induction conclusion to some formula C_i. Either C_i matches directly with the corresponding induction hypothesis term IH or the rippling sequence $C_i \overset{R}{\longmapsto} \ldots \overset{R}{\longmapsto} C_n \overset{R}{\longmapsto} IH$ is computed by backwards reasoning from the induction hypothesis towards C_i. This process is called *reverse rippling*.

For rippling and reverse rippling we use the *rippling–distance* strategy [11, 4]. Each wave-front is mapped to a selected (goal)-sink. The distance between a wave-front and its assigned (goal) sink in the term tree is called *distance measure*. Each application of a wave-rule must reduce this distance until the sink is filled with the wave-front and the distance measure is zero. The main advantage of this approach is the uniform efficient treatment of rippling. Hence, we need not treat the various rippling strategies differently, and it is redundant

to mark the wave-fronts with up-arrows $\uparrow$ and down-arrows $\downarrow$. For uniformly integrating rippling-out the definition of sink has been generalized to arbitrary term positions. By putting a sink around the whole term rippling-out can be simulated by rippling–distance. This approach can be extended easily to incorporate meta-variables. During rippling, meta-variables are treated as potential sink variables. By adopting rippling for meta-variables and using reverse rippling, higher-order variables can be avoided and rippling terminates. For reverse rippling we use the rippling–distance strategy backwards and synthesize a rippling sequence $C_i \overset{R}{\longmapsto} \ldots \overset{R}{\longmapsto} C_n \overset{R}{\longmapsto} IH$ together with a substitution for the meta-variables.

Finally, a consistency checker tests if the remaining subgoals can be proven under the synthesized substitution. If necessary, conditions can be synthesized which constrain the substitution. These *conditional substitutions* form a case split in the proof.

Our approach combines rippling techniques with logical proof search. If it succeeds, the rippling proof is translated back into sequent style.

4 Proving the Specification of the Integer Square Root

In this section we illustrate the automatic instantiation of existentially quantified variables by discussing the proof of the following integer square root specification:

$$\forall x : \mathbb{N}.\ \exists y : \mathbb{N}.\ y^2 \leq x \ \wedge\ x < (y+1)^2 \tag{3}$$

The top–down sequent proof starts by induction on x. We concentrate on the step case of the induction:

$$x : \mathbb{N},\ \exists y : \mathbb{N}.\ y^2 \leq x \ \wedge\ x < (y+1)^2 \quad \vdash \quad \exists y : \mathbb{N}.\ y^2 \leq \mathsf{s}(x) \wedge \mathsf{s}(x) < (y+1)^2$$

This sequent is proved by a procedure which searches for a rippling proof and an instantiation for the existentially quantified variable y. It proceeds as described in figure 1. In the first step, logical inference rules are used in order to decompose the induction hypothesis and the conclusion. The existentially quantified variable in the conclusion is replaced by a meta-variable Y. This gives us two subgoals, (4) and (5):

$$x : \mathbb{N},\ y : \mathbb{N},\ \underline{y^2 \leq x},\ x < (y+1)^2 \quad \vdash \quad Y^2 \leq \boxed{\mathsf{s}(\underline{x})} \tag{4}$$

and

$$x : \mathbb{N},\ y : \mathbb{N},\ y^2 \leq x,\ \underline{x < (y+1)^2} \quad \vdash \quad \boxed{\mathsf{s}(\underline{x})} < (Y+1)^2 \tag{5}$$

During the second step, the goal is annotated in such a way, that its skeleton matches the corresponding part in the induction hypothesis. Corresponding parts are underlined in this example. Note, that the meta-variable Y matches the

variable y in the given. The following wave-rules are derived from the definitions of functions used in the specification:

$$\boxed{\underline{U} + W)} < \boxed{\underline{V} + W)} \overset{R}{\longmapsto} U < V \tag{6}$$

$$\boxed{s(\underline{U})} + V \overset{R}{\longmapsto} \boxed{s(\underline{U + V})} \tag{7}$$

$$(\boxed{s(\underline{A})})^2 \overset{R}{\longmapsto} \boxed{\underline{A^2} + 2A + 1} \tag{8}$$

Note, while in wave-rule (7) and (8) wave-fronts occur on both sides of the wave-rule, in wave-rule (6) the wave-fronts are dropped on the right hand side of the wave-rule. Wave-rules like (6) are usually used to complete proofs[1]. As no wave-rule is applicable, rippling leaves the subgoal unchanged.

The reverse rippling match reasons backwards from the induction hypothesis towards the (rippled) conclusion and extracts a rippling sequence and an instantiation for the meta-variable Y. In the induction hypothesis y is marked as a sink variable. During the first reverse wave-rule application wave-fronts are created by wave-rules of the same type as wave-rule (6). The inserted wave-front is refined step–by–step. This wave-front has to move towards the sink variable y by reverse rippling and results in the instantiation of the meta-variable Y. We start with the second subgoal (5) and try to match $\boxed{\mathsf{s}(\underline{x})} < (Y+1)^2$ (induction conclusion IC – goal) and $x < (y+1)^2$ (induction hypothesis IH – given). The induction hypothesis IH represents the final formula in the rippling sequence. In order to determine which formula preceded the induction hypothesis, the wave-rule set is inspected. The given must match the right hand side of a wave-rule. The left hand side of this rule constitutes the predecessor to IH, if further rippling towards the sink variable is possible. By wave-rule (6) it is suggested that the formula before reaching the induction hypothesis $x < (y+1)^2$ is $\boxed{\underline{x} + W} < \boxed{\underline{(y+1)^2} + W)}$. This formula can be rippled by wave-rule (8) and W can be instantiated with $2(y+1)+1$. The inserted wave-front moves closer to the sink variable y. Rippling towards the sink variable y is straightforward and the generated rippling sequence is presented in Figure 2. By wave-rule (7) the wave-front s is moved to a position where it surrounds y; therefore our rippling sequence terminates successfully. As no wave-rule is available to justify the final step, we need to prove that the induction conclusion is implied by the last step[2]. Typically these implications can be proven by decision procedure using standard arithmetic. In this case the proof is trivial. Therefore $\mathsf{s}(y)$ is a valid substitution for Y.

This substitution and its corresponding rippling sequence (cp. Figure 2) constitute a successful match if the remaining subgoals are true under the found substitution (step 3 in Figure 1). We use a heuristic to check the subgoals and synthesize case splits if necessary. In order to restrict search space, we require

[1] We consider here proofs by strong fertilization, which aim for total match between the induction conclusion term and induction hypothesis term.

[2] The rippling rule $C_i \overset{R}{\longmapsto} C_{i+1}$ corresponds to the logical implication $C_{i+1} \Rightarrow C_i$.

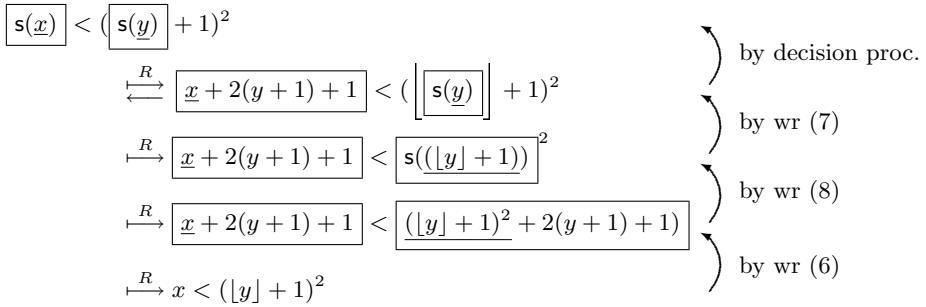


Fig. 2. Rippling sequence generated by extended matching

that the subgoals can be proven by standard arithmetic, rippling and equational reasoning. If one of the remaining subgoals is not provable by these techniques, we use this subgoal as a constraint of the substitutions. In order to be consistent, we then prove all the remaining subgoals under the negated constraint. In this example, (4) is the only remaining subgoal. We use the subgoal $(\mathsf{s}(y))^2 \leq \mathsf{s}(x)$ as a constraint, and therefore try to prove both cases (4) and (5) for the case $\neg(\mathsf{s}(y))^2 \leq \mathsf{s}(x)$. We use unfolding of the successor and $\neg(\ldots \leq \ldots)$ function s and normal matching, to derive a substitution. We start again by inspecting subgoal (5). Matching between $\mathsf{s}(x) < (Y+1)^2$ and $\mathsf{s}(x) < (y+1)^2$ returns the substitution $[y/Y]$. The subgoal (4) is trivially true under this substitution.

By combining logical proof search with rippling and extended matching, we are able to generate automatically a proof for the step case and to synthesize a set of conditional substitutions:$[(\mathsf{s}(y))^2 \leq \mathsf{s}(x), \mathsf{s}(y)/Y], [\neg((\mathsf{s}(y))^2 \leq \mathsf{s}(x)), y/Y]$.

5 An Algorithm for Extended Matching

In this section we present a technical description of the steps performed during the automatic instantiation of existentially quantified variables (see Figure 1). We use ML-notation to describe the algorithm. To automate step 1 standard theorem proving methods can be used. We concentrate on the extended matching procedure (step 2 and 3) which is the core of the automatic instantiation of existentially quantified variables.

Before calling the algorithm extended_matching, the wave-rule set wrs contains potential wave-rules. The wave-rules are annotated dynamically during the rippling and reverse rippling process. The function extended_matching returns (conditional) substitutions and proofs, if

1. The list of subgoals, sgoal_list, contains at least one element sgoal. In this case calling rippling_sequence (conclusion sgoal) (hypothesis sgoal) wrs finds a rippling sequence rip_seq and a substitution subst (Figure 3); (conclusion sgoal) gives us the rippled conclusion and (hypothesis sgoal) returns the corresponding hypothesis.

2. the remaining subgoals, sgoal_list\{sgoal}, are consistent with this substitution (check_subgoals sgoal_list sgoal subst).

The function rippling_sequence, described in Figure 3, computes a rippling sequence rip_conc $\stackrel{R}{\longmapsto} \ldots \stackrel{R}{\longmapsto} \ldots C_i \stackrel{R}{\longmapsto} \ldots \stackrel{R}{\longmapsto}$ ind_hyp and a substitution for the meta-variable. First the variable in the induction hypothesis that corresponds to

```
let rippling_sequence conc ind_hyp wrs =
let ann_conc = annotate conc ind_hyp in
let rip_conc = ripple ann_conc wrs in
let predecessors = poss_predecessors ind_hyp rip_conc wrs in
letrec reverse_rippling_in path predecessors =
        if predecessors = [ ] & filled_sink (hd path) & (hd path) → rip_conc
          then path
          else select p ∈ predecessors
                let new_predecessors = poss_predecessors p wrs in
                    reverse_rippling_in p::path new_predecessors in
reverse_rippling_in [ ] predecessors
```

Fig. 3. Algorithm for synthesizing rippling sequence $C_n \stackrel{R}{\longmapsto} \ldots IH$

the meta-variable in the induction conclusion is marked with a sink. The function poss_predecessors computes possible predecessors C_{i-1} for a given formula C_i in the rippling sequence by inspecting the wave-rule set wrs. It simulates the backwards application of one rippling rule. The function reverse_rippling_in triggers the reverse rippling process. It proceeds recursively by depth first search if there are several predecessors to a formula. It reasons backwards from the induction hypothesis ind_hyp towards the rippled conclusion rip_conc. In each recursion, the next possible predecessors are computed. It is successful if the sink variable is surrounded by a wave-front, i.e. the sink is filled and this formula C_{i+1} implies C_i. Otherwise backtracking is initiated.

The function check_subgoals checks if the remaining subgoals are provable under the substitution derived by rippling_sequence. If all the remaining subgoals can be proven under the substitution, then the match is successful. If there are subgoals that are not provable by a simple proof procedure simplify[3], then we use one of the remaining unprovable subgoal as a constraint c and prove
1. each g ∈ sgoal_list \{sgoal}. g is provable by simplify under the constraint c
2. each g ∈ sgoal_list. g is provable by simplify and matching under constraint ¬c.
With the presented algorithm we are able to instantiate existentially quantified variables automatically and solve the step case of an inductive proof automatically. Moreover, by a simple heuristic, which is integrated in check_subgoals we are able to synthesize conditional substitutions. These conditions form a case split in the proof. For a more detailed version we refer to [15].

[3] simplify is a combination of NuPRL's tactics Unfold, SupInf and Auto. It is a decision procedure that uses standard arithmetic.

6 Integrating into NuPRL

In this section we discuss the integration of our proof method into NuPRL, an interactive, tactic based theorem prover. The described proof procedure is implemented and embedded within the tactic TReverseRipple. If the proof procedure finds a substitution for the meta-variables and all the subgoals can be solved, this proof is translated back into sequent style. Due to the nature of reverse rippling, the eigenvariablen condition is observed, and does not cause any problems for the back translation.

The sequent-style proof in NuPRL for the integer square root specification is presented in Figure 4. In this proof the user specified the induction scheme.

Fig. 4. Proof of the integer square root in NuPRL

First, the universal quantifier on the right hand side is decomposed by tactic allR. The tactic TNatInd 'x' then splits the conjecture into base and step case. Our automation efforts concentrate on the step case of the induction. The step cases of an induction proof are challenging for mainly two reasons: 1) It is harder than in the base case to find the witness for the existentially quantified variable(s). 2) Sometimes, a case split is required and the existentially quantified variable is instantiated according to the different cases. These case splits are not immediately obvious, and often require user insight.

The tactic TReverseRippling synthesizes a conditional substitution set for the existentially quantified variable and translates this information into a sequent proof. The proof displays the subtactics which were applied by TReverseRipple. A case split is performed by tactic Decide based on the conditional substitution set before instantiating the existential quantifier on the right hand side. The tactic exL decomposes the existential quantifier on the left hand side. Applications of tactic andL resp. andR eliminate the conjunction on the left resp. right hand side. The generated rippling sequence is translated back into sequent proof by cut, substitution and lemma applications as described in [11].

7 Extensions to Reverse Rippling

Examples, that can be solved by our method include the specification of quotient remainder, append, half, or last. These examples span the range of specifications usually considered (see [5, 10, 16]) and do not require any case splits. We also can prove the specification for $\log_2$ which results in a similar proof to the integer square root example. Moreover, we used the extended matching procedure to instantiate universally quantified variables in the hypothesis list. With this extension we are also able to prove the specification of the integer square root and $\log_2$ by using non-standard induction schemes allowing us to synthesize while loops for these two specifications.

To illustrate the flexibility and strength of our technique, we prove the integer square root specification by a different induction scheme[4]. In the step case (induction proceeds over k) we yield the following conjecture:

$$k:\mathbb{N}, \forall x,y{:}\mathbb{N}.\ x{-}y < \mathsf{p}(k) \wedge y^2 \leq x \wedge 0 \leq y \Rightarrow \exists n{:}\mathbb{N}.\ y \leq n \wedge n^2 \leq x \wedge x < (n+1)^2$$
$$\vdash \forall x,y{:}\mathbb{N}.\ x{-}y < k \wedge y^2 \leq x \wedge 0 \leq y \Rightarrow \exists n{:}\mathbb{N}.\ y \leq n \wedge n^2 \leq x \wedge x < (n+1)^2$$

Rippling would annotate the term $x{-}y < k$ to give $\lfloor x \rfloor - \lfloor y \rfloor < \boxed{\mathsf{s}(\mathsf{p}(\underline{k}))}$ as it operates on the induction conclusion. However, no rippling proof for the left hand side of the sequent can be found. Our approach first decomposes the right and left hand side and then uses extended matching to find a match between $x{-}y < k$ in the hypothesis list and $X{-}Y < \mathsf{p}(k)$ on the conclusion side. By reverse rippling starting from $x{-}y < k$ we try to generate a rippling sequence and an instantiation for X and Y. The following additional wave-rules are derived from monotonicity laws and the definition of $-$ is provided:

$$V > 0 \wedge U > 0 \Rightarrow \boxed{\mathsf{p}(\underline{U})} < \boxed{\mathsf{p}(\underline{V})} \overset{R}{\longmapsto} U < V \tag{9}$$

$$\boxed{\mathsf{p}(\underline{U{-}V})} \overset{R}{\longmapsto} U{-}\boxed{\mathsf{s}(\underline{V})} \tag{10}$$

By wave-rule (9) and wave-rule (10) the extended matching procedure generates the following rippling sequence:

$$x{-}\boxed{\mathsf{s}(\underline{y})} < \boxed{\mathsf{p}(\underline{k})} \quad \overset{R}{\underset{(10)}{\longmapsto}} \quad \boxed{\mathsf{p}(\underline{x{-}y})} < \boxed{\mathsf{p}(\underline{k})} \quad \overset{R}{\underset{(9)}{\longmapsto}} \quad x{-}y < k$$

[4] This induction scheme will result in a more efficient program, namely a while loop. In each iteration y is incremented until $(y+1)^2 > x$.

This example illustrates that the conventional rippling approach [7] to instantiate universally quantified variables in the induction hypothesis by rippling-in is not expressive enough. Moreover, it supports the strength of our approach. The combination of logical proof search and rippling gives us the flexibility to deal with complex logical formulas.

8 Related Work

One of the first approaches to automate the instantiation of existentially quantified variables has been by Biundo [5]. Existentially quantified variables are replaced by Skolem functions which describe the program which is to be synthesized. After induction the formula in the step case is put into clausal form. The synthesis proceeds by *clause–set translations* (e.g. rewriting and case splitting) which induce an AND/OR search space. The work of Kraan *et al.*[10] builds upon the idea to replace existentially quantified variables by skolem functions in order to synthesize logical programs. In order to control better the search space within the inductive step, rippling and middle–out reasoning [9] are used to construct predicate definitions from specifications in classical logic. However, both approaches do not guarantee that the synthesized program is correct, it has to be verified after the synthesis. We believe that constructive type theory provides a firmer mathematical foundation than is found in these systems.

In Smaill & Green [16], an approach for the synthesis of functional programs within the framework of constructive type theory is suggested. This approach builds on higher–order embeddings and higher–order rippling. Middle-out reasoning and higher order embeddings have the disadvantage of a big search space, as rippling in the presence of higher-order function variables does not terminate.

The rippling approaches rely exclusively on this technique and encode logical inference rules as wave-rules. The whole induction conclusion is rippled and these systems aim for a match of the whole induction conclusion with the entire induction hypothesis. The underlying logical calculus is not used to decompose the step case during proof search. This causes major problems when we deal with specifications of more complex formulas, as we illustrated in section 7.

9 Conclusion and Future Work

We have presented an approach for the instantiation of existentially quantified variables which provides a significant degree of automation to proofs in constructive type theory. The key idea is to use first-order meta-variables in place of the existential witness during proof search and rippling and instantiate this meta-variable by an extended matching procedure. Because we reason backwards from the induction hypothesis towards the rippled conclusion by reverse rippling, our approach is highly goal directed and we are able to synthesize lemmata during reverse rippling. By combining logical proof search methods with rippling techniques, we gain flexibility and are able to synthesize case splits which cannot be derived by other comparable systems.

We see our work in a more general framework of matching: two terms t_1 and t_2 match, if the meta-variables in t_1 can be instantiated in such a way that rippling rewrites t_1 towards t_2. This approach allows us to treat meta-variables uniformly. We plan to extend and refine our method in this direction.

Moreover, we plan to explore the use of specially tailored logical proof search methods such as connection method [14] or resolution [17] instead of direct proof search in the sequent calculus. These proof methods are more goal directed. For future research we aim to combine these techniques with a matching procedure which uses rippling and reverse rippling techniques.
